Figure S1. The presence of hematogones marks a group with good prognosis in patients in ALL and lymphoma patients who failed to achieve remission prior to HSCT.

The Kaplan–Meier estimates of OS and RFS in HG+ and HG− patients in ALL (A) and lymphoma (B), differentiated with their remission status prior to HSCT. Despite limited numbers of patients, statistically significant better OS and RFS were seen in the HG+ groups as compared to the HG− groups.
